Outline

- The Sivers effect in SIDIS
- Extraction of the Sivers function in a Gauss model
- Antiquark Sivers function
- Transverse SSA @ RHIC
- Consistency Check of Large N_C ansatz
- Conclusions

Unweighted Sivers asymmery

need model for p_T- dependence of distribution functions !

$$\begin{array}{c} p_{urap}^{2} \longrightarrow \text{HERMES } \mathbf{P}_{h\perp} \text{ data} \\ \langle \mathbf{P}_{h\perp}(z) \rangle \stackrel{Gauss}{=} \frac{\sqrt{\pi}}{2} \sqrt{z^{2} p_{urap}^{2} + K_{D1}^{2}} \\ p_{urap}^{2} = 0.33 \text{ GeV}^{2} \\ K_{D1}^{2} = 0.16 \text{ GeV}^{2} \\ \end{array}$$

$$\begin{array}{c} \textbf{P}_{urap} = 0.33 \text{ GeV}^{2} \\ K_{D1}^{2} = 0.16 \text{ GeV}^{2} \\ \textbf{P}_{urap} = 0.16 \text{ G$$

Extraction

positivity condition gives us only a vague value for p_{aiv}^2

F

<u>BUT:</u> If we use the first Sivers moment instead of the unweighted Sivers function, one gets

$$\begin{aligned} A_{UT}^{\sin(\phi_{b}-\phi_{S})} &= (-2) \frac{a_{Gauss} \sum_{a} e_{a}^{2} x f_{1T}^{\perp(1)a}(x) D_{1}^{a}(z)}{\sum_{a} e_{a}^{2} x} \sum_{a} \int dx f_{1T}^{\perp(1)a} = 0 \qquad a_{Gauss} = \frac{\sqrt{\pi}}{2} \frac{M_{N}}{\sqrt{p_{siv}^{2} + \frac{K_{D1}^{2}}{x^{2}}} \\ \text{and} \qquad 0.72 < a_{Gauss} < 0.83 \qquad \text{only 10\% uncertainty !!!} \\ \hline T: \qquad x f_{1T}^{\perp(1)u}(x) = -x f_{1T}^{\perp(1)d}(x) = A x^{b} (1-x)^{5} \\ f_{1T}^{\perp(1)\bar{q},g}(x) = 0 \qquad 0 \end{aligned}$$

$$\begin{aligned} \text{choose } 0 < p_{siv}^{2} < 0.33 \\ \text{check positivity} \qquad \qquad \frac{|\mathbf{p}_{T}|}{M} \left| f_{1T}^{\perp a}(x, \mathbf{p}_{T}^{2}) \right| \le f_{1}^{a}(x, \mathbf{p}_{T}^{2}) \end{aligned}$$

Results

Results

Positivity Condition is fulfilled!

Antiquarks	
• up to now $f_{1T}^{\perp ar{q}} = 0$	
QUESTION: Is it justified to neglect the ant	iquark distributions?
invent two models for Sivers antiquar	< distributions
 (1) <u>simple model</u>: Antiquarks have the same distribution like quarks, but only with 25% amplitude 	
(2) <u>advanced model</u> : The ratio of antiquarks Sivers function is the same as the	
unpolarized ratio	0.25 Model I
$f_{1T}^{\perp ar{q}}(x) = \epsilon(x) f_{1T}^{\perp q}$	$\begin{array}{ll} \epsilon(x) &= \pm \\ & \frac{\left(f_1^{\bar{u}} + f_1^{\bar{d}}\right)(x)}{\left(f_1^{u} + f_1^{d}\right)(x)} & \text{Model II} \end{array}$
Burkardt sum rule is automatically obeyed!	

Size of errorbars does not allow one to extract Sivers antiquark distribution functions!

 $f_{1T}^{\perp \bar{q}} = 0$?? is not fixed. (Anselmino et al, Vogelsang, Yuan)

Sivers asymmetry in Drell-Yan

based on the present understanding of T-odd distribution functions, one can make a QCD prediction:

<u>Collins 2002</u>:

$$\left| f_{1T}^{\perp}(x) \right|_{SIDIS} = - \left| f_{1T}^{\perp}(x) \right|_{DY}$$
(#)

Can make predictions for DY based on (#) and

$$\epsilon(x) = \pm \begin{array}{c} 0.25 \quad \text{Model I} \\ \frac{\left(f_1^{\bar{u}} + f_1^{\bar{d}}\right)(x)}{\left(f_1^{u} + f_1^{d}\right)(x)} \quad \text{Model II} \end{array}$$

$$f_{1T}^{\perp \bar{q}}(x) = \epsilon(x) f_{1T}^{\perp q}$$

Predictions for Drell-Yan

Visibility of Sivers antiquarks

- PAX: collision of protons and antiprotons
- <u>COMPASS</u>: collision of protons and negative pions

sivers antiquark distribution hardly visible !

RHIC: DY process with pp - Collisions:

sensetive to on equal footing $f_{1T}^{\perp(1)q}(x_1)f_1^{\bar{q}}(x_2)$ and $f_1^q(x_1)f_{1T}^{\perp(1)\bar{q}}(x_2)$

Sivers antiquark distributions should be visible @ RHIC

DY @ STAR

Conclusions

- A parameterization of the u-quark Sivers function has been extracted
- Change of sign of Sivers asymmetry visible in DY
- A parameterization of the antiquark Sivers function can not be extracted from COMPASS or HERMES data
- Can be extracted from RHIC data (PHENIX, STAR)
- Errors @ STAR should be small enough to get a good parameterization
- Large N_C Model ist compatible with present data
